Abstract—We consider a setup where a rechargeable battery is used to partially mask the load profile of a user from the utility provider in a smart-metered electrical system. We focus on the case of i.i.d. load profile, use mutual information as our privacy metric, and characterize the optimal policy as well as the associated leakage rate.

Our approach is based on obtaining single-letter expression for the leakage rate for a class of battery policies and providing a converse argument for establishing the optimality.

I. INTRODUCTION

Smart meters are becoming a critical part of modern electrical grids. They deliver fine-grained household power usage measurements to utility providers. This information allows them to implement changes to improve the efficiency of the electrical grid. However, despite the promise of savings in energy and money, there is potentially a loss of privacy. Anyone with access to the load profile may employ data mining algorithms to infer details about the private activities of the user [1]–[4].

In this paper, we investigate one possible solution to the privacy problem. Using a rechargeable battery, the user can distort the load profile generated by the appliances by charging and discharging the battery. Due to the proliferation of rechargeable batteries, energy harvesting devices and electric vehicles, the strategy of using these devices to partially obfuscate the user’s load profile is becoming more feasible. As we discuss below, a number of recent works have studied this approach in the literature.

A. Related Works

We consider a similar setup to [7] which introduces using mutual information as a privacy metric then considers an instance of the problem with binary alphabets. The setup is extended in [8], [9] where the multi-letter mutual information optimization problem is reformulated as a Markov Decision Process. The results in this paper mirror that of [10] where the optimal single-letter information leakage rate and policy is characterized using Markov Decision Theory. In this paper, we provide the proofs using purely information theoretic arguments which may be of interest in its own right.

In other related works, rate-distortion type approaches for studying privacy-utility tradeoffs in smart grid systems have been studied in [11]–[12]. These works are not directly related to the present setup.

II. PROBLEM DEFINITION

We consider a smart metering system as shown in Fig. 1 where at each time a residence generates an aggregate demand that must either be satisfied by charges in the battery or by drawing power from the grid. \( \{X_t\}_{t \geq 1} \) where \( X_t \in X \) where \( X := \{0, 1, 2, \ldots, m_x\} \) denotes the (exogeneous) i.i.d. power demand process distributed according to \( Q_X. \) \( \{Y_t\}_{t \geq 1} \) \( Y_t \in Y, \) denotes the energy consumed from the grid where \( Y := \{0, 1, 2, \ldots, m_y\} \) and \( \{S_t\}_{t \geq 1}, S_t \in S \) denotes the energy stored in the battery where \( S := \{0, 1, 2, \ldots, m_s\} \) and the initial charge \( S_0 \) of the battery is distributed according to probability mass function \( P_{S_0}. \)

We assume that \( m_x \leq m_y \) so that the system is guaranteed to be able to satisfy the demand at any time by drawing solely from the grid i.e. \( Y_t = X_t, \forall t. \) While in general, the alphabets \( X \) and \( Y \) can be any finite subset of the integers – where negative values of \( X \) and \( Y \) would model a situation where energy (possibly generated from an alternative energy source) is sold back to the utility provider – it is more realistic to for them to be a contiguous interval. In this case, without further assumptions on the battery size, the alphabets would have to satisfy \( X \subset Y \) in order to guarantee that energy is not wasted and the power demand can always be satisfied. Nonetheless, our results generalize to these cases.

We assume an ideal battery that has no conversion losses or other inefficiencies. Therefore, the following conservation equation must be satisfied at all time instances:

\[
S_{t+1} = S_t - X_t + Y_t. \tag{1}
\]

The energy management system observes the power demand and battery charge and consumes energy from the grid according to a randomized charging policy \( \mathbf{q} = (q_1, q_2, \ldots). \) In particular, at time \( t, \) given \( (x^t, s^t, y^{t-1}) \), the history of demand, battery charge, and past consumption, the battery policy chooses the level of current consumption \( Y_t \) to be \( y \) with probability \( q_t(y \mid x^t, s^t, y^{t-1}) \). For a randomized charging policy to be feasible, it must satisfy the conservation
equation (1), so given the current power demand and battery charge \((x_t, s_t)\), the feasible values of grid consumption are defined by
\[
\mathcal{Y}_0(s_t - x_t) = \{y \in \mathcal{Y} : s_t - x_t + y \in S\}.
\]

Thus, we require that
\[
q_t(y_{s_t - x_t} | x^t, s^t, y^{t-1}) := \sum_{y \in \mathcal{Y}_0(s_t - x_t)} q_t(y | x^t, s^t, y^{t-1}) = 1.
\]

The set of all such feasible strategies is denoted by \(Q_A\). A battery policy effectively defines a channel with memory between a residence and the utility provider (as portrayed in Fig. 1).

The quality of a charging policy depends on the amount of information leaked under that policy. This notion is captured by mutual information and is denoted by the conditional distribution \(q(Y_t | X^t, S^t, Y^{t-1})\). The battery policy effectively defines a channel with memory from the residence to the utility provider.

III. STATIONARY POSTERIOR POLICIES

The simplest class of policies are stationary and memoryless, conditioning only on the current battery state and power demand:
\[
q(y | x, s).
\]

As such evaluating the leakage rate \(L_\infty(q)\) even for this simplified class of policies requires numerical approaches, see e.g., \(\cite{7, 13}\). Our key insight is that if we further impose a certain invariance condition we can obtain a closed form expression for the leakage rate. Interestingly we will see that this class of policies also includes a globally optimal policy. Our proposed class preserves the following property:
\[
P(S_2 = s_2 | Y_1 = y_1) = P(S_1 = s_2), \quad \forall s_2 \in S, y_1 \in \mathcal{Y}
\]

where \(\mathcal{Y} := \{y : P_{Y_1}(y_1) > 0\}\) for some initial battery state distribution \(P_{S_1}\). This invariance condition implies that \(S_t \perp Y_{t-1}\) and also that \(P_{S_t} = P_{S_0}, \forall t\). By exploiting this property, we can obtain single-letter achievable leakage rates as follows:

**Lemma III.1.** Given an instance of Problem A with i.i.d. power demand \(Q_X(x)\) and initial battery state distribution \(P_{S_0}\), if the stationary memoryless policy \(q = (q_1, q_2, \ldots) \in Q_A\) satisfies the invariance property \(5\), then
\[
L_\infty(q) = I^q(S_1, X_1; Y_1),
\]

where \((S_1, X_1, Y_1) \sim P_{S_1}(s_1)Q_X(x_1)q(y_1 | x_1, s_1)\).

**Proof.** The invariance property and the memorylessness of \(q\) implies that \((Y_t, X_t, S_t) \perp \!\!\!\perp Y_{t-1}, \forall t\). Therefore we have
\[
\frac{1}{T} I^q(S_1, X^T; Y^T) = \frac{1}{T} \sum_{t=1}^{T} I^q(S^t, X^T; Y^T) = \frac{1}{T} \sum_{t=1}^{T} I^q(S^t, X^T; Y^T) = \frac{1}{T} I^q(S_1, X_1; Y_1)
\]

where (a) is due to the chain rule of mutual information and the fact that \(S^t\) is a deterministic function of \((S_1, X_1^t, Y_1^{t-1})\) given by the battery update equation (1), (b) is due to the invariance property (5), and (c) is due to the memoryless condition (4).

We will next develop some further properties of the invariance condition (5). Let us define an auxiliary random variable
\[
W_t := S_t - X_t \text{ where } W_t \in \mathcal{W} := S - X \text{ and for } w \in \mathcal{W}, \text{ let } D(w) := \{(x, s) \in X \times S : s - x = w\}.
\]

**Lemma III.2.** An initial battery distribution \(P_{S_1}\) and a stationary memoryless policy \(q = (q_1, q_2, \ldots) \in Q_A\) satisfies the invariance property \(5\) if for each \((s_2, y_1) \in S \times X\), we have
\[
P_{S_1}(s_2)Q(y_1) = \sum_{(\tilde{x}, \tilde{s}) \in D(s_2 - y_1)} q(y_1 | \tilde{x}_1, \tilde{s}_1)Q(\tilde{x}_1)P_{S_1}(\tilde{s}_1).
\]
Proof. (If) Note that since the rhs is equal to the joint \(P^q(S_2 = s_2, Y_1 = y_1)\), the systems of equations in the Lemma implies that \(S_2 \perp Y_1\) and \(P^q_{S_2} = P^q_{S_1}\) which is the invariance property [5].

(Only if) Assuming the invariance property to be true, since \(S_1 - X_1 = S_2 - Y_1\) given by the battery update equation [1] we must have \(P^q_{Y_1}(y_1) = Q(y_1), \forall y_1 \in X\). Using Bayes rule and the definition of the joint distribution we recover the statement in the Lemma.

Lemma III.2 implies that the alphabet for \(\{Y_1\}_{t>0}\) must be limited to \(X\) and \(P^q_{Y_1} = Q\). In addition, Eq. (6) provides an explicit condition that must be satisfied by the stationary memoryless policies for any fixed \(P_{S_1} \in \mathcal{P}_S\). Note that these are essentially \(|W|\) linear constraints. It should be clear that these constraints are always feasible. For example, using the policy \(Y_t = X_t\), any \(P_{S_1}\) will satisfy the invariance property [5]. However, this will maximize the leakage rate. We next discuss a policy that turns out to be optimal.

A. Optimal Policy

**Lemma III.3.** Given a fixed \(P_{S_1}\) and \(W_1 = S_1 - X_1\), the optimal policy \(q^* = (q^*, q^*\ldots)\) satisfying the invariance property [5] is

\[ q^*(y|x,s) = \begin{cases} Q(y)P_{S_1}(y+s-x)P_{W_1}(s-x) & \text{if } y \in X \cap \mathcal{V}_c(s-x) \\ 0 & \text{otherwise} \end{cases} \]

achieving a leakage rate of

\[ L_{\infty}(q^*) = I(S_1 - X_1; X_1) \]

where \((S_1, X_1) \sim P_{S_1}(s_1)Q(x_1)\).

**Proof.** By definition, \(q^*(y|x,s) \geq 0, \forall s \in S, x \in X, y \in X \cap \mathcal{V}_c(s-x)\). Next, we show that \(q^*\) is properly normalized.

\[
\sum_{\tilde{y} \in X \cap \mathcal{V}_c(s-x)} Q(\tilde{y})P_{S_1}(\tilde{y} + s - x) = \sum_{(\tilde{x}, \tilde{s}) \in D(s-x)} Q(\tilde{x})P_{S_1}(\tilde{s}) = \text{Denominator of } q^*(\mathcal{V}_c(s-x)|x,s),
\]

where the second step follows by substituting \(\tilde{x} = \tilde{y}\) and \(\tilde{s} = \tilde{y} + s - x\) and observing that \(\tilde{s} - \tilde{x} \in D(s-x)\). Therefore, \(q^*\) is admissible. The invariance property can be verified using Lemma III.2 or as follows:

\[
P^q_{S_2} = P^q_{S_2} = P^q_{S_1}
\]

where (a) and (b) use the fact that \(S_2 - Y_1 = W_1\) holds from the battery update equation, (c) is because \(q^*(y|x,s)\) only depends on \((x,s)\) via \(s - x\) and the last equality follows from the definition of \(q^*\). The last equality shows that the invariance property is satisfied.

To show optimality, fix \(P_{S_1}\) and let \(q^*\) be any policy satisfying Lemma III.2 and consider the following inequalities:

\[ L_{\infty}(q^*) \leq I(S_1, X_1; Y_1) \leq H(W_1) - H(W_1 + Y_1) \]

\[ \leq H(W_1) - H(S_2) \]

\[ \leq H(W_1) - H(S_1 - X_1) \]

\[ = I(S_1 - X_1; X_1) \]

(a) is due to Lemma III.2, (b) is due to the data processing inequality, (c) and (d) are due to the battery update equation (1) and the invariance property of \(q^*\), and (e) is by definition.

The achievability proof is completed by noting that under \(q^*\), we have \(Y_t - W_t = (X_t, S_t)\) and so the lower bound is obtained.

**Proposition III.1.** Minimizing over the initial battery distribution \(P_{S_1}\) in Lemma III.3 we obtain the optimal leakage rate in the class of policies satisfying the invariance property [5].

**Remark III.1.** The limitation of this achievability scheme requires that the battery have a specific distribution over the battery's initial states. However, this loss of generality is operationally insignificant since the user can start off by randomly charging the battery from an external source.

B. Converse

So far we have shown that the policy in Lemma III.3 is optimal for the class of invariance policies that satisfy (5). We will now prove an information theoretic converse that establishes that the stated policy is globally optimal among all policies in \(Q_A\). This provides the counterpart of the result in [10], but avoids the use of the dynamic programming framework. Consider the following inequalities: for any admissible policy \(q \in Q_A\) we have

\[
I(S_1, X^T; Y^T) \geq \sum_{t=1}^{T} I(S_t, X_t; Y_t|Y^{t-1}) \geq \sum_{t=1}^{T} I(W_t; Y_t|Y^{t-1})
\]

\[
= H(W_1) - H(W_1|Y_1) + H(W_2|Y_1) - H(W_2|Y_2) + \cdots
\]

\[
= H(W_1) - H(S_2|Y_1) + H(S_2 - X_2|Y_1) - H(S_3|Y_2) + \cdots
\]

\[
= H(W_1) + \sum_{t=2}^{T} I(W_t; X_t|Y^{t-1}) - H(W_T|Y^T)
\]
where (a) is because $S_{t+1}$ is an invertible function of $W_t$ given $Y_t$. Now, taking the limit $T \to \infty$ to obtain a lower bound to the leakage rate we have

$$L_\infty(q) = \lim_{T \to \infty} \frac{1}{T} I(S_1, X^T; Y^T) \geq \lim_{T \to \infty} \frac{1}{T} \left[ H(W_1) + \sum_{t=2}^{T} I(W_t; X_t| Y^{t-1}) - H(W_T| Y^T) \right].$$

(a)\[ \geq \lim_{T \to \infty} \frac{1}{T} \sum_{t=2}^{T} I(W_t; X_t| Y^{t-1}) \]

(b)\[ \geq \min_{P_S \in \mathcal{P}_S} I(S-X; X). \]

(a) because the entropy of any discrete random variable is bounded and (b) follows from the observation that every term in the summation is only a function of the posterior $P(S_t| Y^{t-1})$. Therefore, minimizing each term over a $P_S \in \mathcal{P}_S$ results in a lower bound to the optimal leakage rate which is achievable using Proposition III.1.

IV. Conclusions

In this paper, we provide a single-letter characterization of the optimal private information leakage rate using information theoretic arguments. While the result was already established in [10], the proof provided in this paper is based on more elementary arguments and avoids the use of the dynamic programming framework. Our proof shows that the optimal leakage rate is achieved using a class of stationary memoryless policies that preserve the posterior distribution of the battery state. We believe that the techniques discussed here also extend to continuous valued input and output alphabets.
